**A COMPREHENSIVE STUDY OF BREAST CANCER PATIENTS
OF PAKISTAN****¹Dr. Tahira Perveen, ¹Dr. Humaira Perveen, ¹Dr. Iftikhar Javed**¹Demonstrator Pharmacology, BAMDC Multan²Demonstrator Community Medicine, BAMDC Multan³Nishter Medical University, Multan**Abstract**

Introduction: Women with a diagnosis of advanced breast cancer engage in a multi-stage cancer treatment cycle often involving surgery, radiation treatment and chemotherapy. These cycles of treatment are not free of side effects.

Aims and objectives: The basic aim of the study is to analyze about the breast cancer patients among local female population of Pakistan.

Material and methods: This study was conducted at BAMDC Multan, during 2017 to 2018. Using a purposive sampling strategy, 14 adult female breast cancer patients were selected for this study with variations in their age, educational level, socioeconomic status, and number of exposures to RT.

Collection of data: Data were collected through the recording of the face-to-face in-depth interviews, using a semi-structured interview guide.

Results: A total of 14 female breast cancer patients participated in this study. Their age ranged between 20 and 60 years, with an average of 35 years. Majority (79%) of them were married. About 50% of them were illiterate, whereas 43% were matriculate. All of them were Muslims and of Pathan ethnicity. Before RT, all of them had mastectomy of the affected breast, followed by chemotherapy. Analysis of the interviews data each category and its subcategories are described below with some excerpts from the participants' narratives.

Conclusion: It is concluded that a substantial number of adult cancer patients were depressed and have a suicidal ideation, causing a significant functional impairment.

INTRODUCTION:

Women with a diagnosis of advanced breast cancer engage in a multi-stage cancer treatment cycle often involving surgery, radiation treatment and chemotherapy. These cycles of treatment are not free of side effects. Women have to face possible disfigurement, surgical pain, the side effects from chemotherapy which can include feelings of anger, frustration, fear, isolation, fatigue as well as burns from targeted radiotherapy [1]. Globally, breast cancer is the most common cancer among women, and also a leading cause of cancer-related deaths in this gender. It accounts for 23% of all cancer cases worldwide. The incidence of breast cancer has been increasing rapidly in the developing countries. Among the Asian countries, Pakistan has the highest prevalence of breast cancer, where one in every nine women is at risk of developing breast cancer [2]. In western countries, breast cancer is prevalent among women aged 60 years and above, whereas, in Asian countries, including Pakistan, it occurs during the reproductive age between 30 and 50 years. Hence, women with breast cancer, in Pakistan, may face more challenges due to household and child-rearing responsibilities, as compared to those living in the western countries [3]. According to the American Society for Radiation Oncology, radiotherapy (RT) is a common treatment modality for cancer which is prescribed to about two-thirds of the cancer patients, either before or after surgery. In breast-conserving surgery, RT reduces the chances of recurrence as well as the risk of metastasis and death from breast cancer [4,5].

Aims and objectives

The basic aim of the study is to analyze about the breast cancer patients among local female population of Paksitan.

Material and methods

This study was conducted at BAMDC Multan, during 2017 to 2018. Using a purposive sampling strategy, 20 adult female breast cancer patients were selected

for this study with variations in their age, educational level, socioeconomic status, and number of exposures to RT.

Collection of data

Data were collected through the recording of the face-to-face in-depth interviews, using a semi-structured interview guide. Questions included the following: When you found out that your disease was advanced, how did you react? What is keeping you motivated to cope with your illness? Has this disease changed your perception regarding life? What is the most important goal for you to achieve in life? Interviews were digitally recorded (TT). Iterative cycles of data collection and data analysis were undertaken this continued until data saturation occurred after 21 interviews. At this time no new findings were emerging during interviews, therefore interviews were terminated. Patients with the breast cancer differ significantly in time of relapse despite the fact that nature of tumors was similar at initiation of breast cancer.

Statistical analysis

Student's t-test was performed to evaluate the differences in roughness between group P and S. Two-way ANOVA was performed to study the contributions. A chi-square test was used to examine the difference in the distribution of the fracture modes (SPSS 19.0 for Windows, SPSS Inc., USA).

RESULTS:

A total of 20 female breast cancer patients participated in this study. Their age ranged between 20 and 60 years, with an average of 35 years. Majority (79%) of them were married. About 50% of them were illiterate, whereas 43% were matriculate. All of them were Muslims and of Pathan ethnicity. Before RT, all of them had mastectomy of the affected breast, followed by chemotherapy. Analysis of the interviews data each category and its subcategories are described below with some excerpts from the participants' narratives.

Table 01: Demographic characteristics of participants

Variables	Frequency (%)
Age (years)	
20-29	5 (35.71)
30-39	4 (28.57)
40-49	4 (28.57)
50-60	1 (7.14)
Marital status	
Married	11 (78.57)
Unmarried	2 (14.29)
Widowed/divorced	1 (7.14)
Educational status	
Illiterate	7 (50.00)
≤10 th grade	6 (42.86)
>10 th grade	1 (7.14)
Social status	
Homemakers	13 (92.86)
Working woman	1 (7.14)

Table 02: Findings of the interview

Categories	Subcategories
Feelings and perceptions	Grief and sorrow
	Shame and guilt
	Fear and anxiety
	Uncertainty of treatment
Challenges faced by women	Role performance
	Emotional instability
	Access and affordability of treatment
	Faith and prayers
Coping strategies	Family support
	Mind diversion
Teaching and informational needs	Source of information
	Quality of information

DISCUSSION:

Breast cancer is second most prevalent type of cancer and is equally common in developing as well as developed countries. The treatment expenditure of breast cancer is a burden not only for people diagnosed with cancer but also for their families and society as a whole. According to American Cancer Society (2010) breast cancer is one of the top three types of cancer that caused the most economic impact (\$88 billion) [6].

Though successful treatment options are available to deal with breast cancer, pain and suffering associated with available treatment modalities is significant. Chronic, persistent pain acts as an additional stressor for a person already suffering from many psychological, social and medical stressors [7]. Research has demonstrated association between

clinically relevant pain and breast cancer surgery in 10-50% patients. There are pathogenic mechanisms involved in breast cancer like nerve damage and certain sensory disturbances (e.g., burning and sensory loss) are part of side effects of surgical processes [8]. Breast cancer surgery is followed by chronic neuropathic pain syndrome like Phantom breast pain (a sensory experience that is present even after removal of breast and is painful), Inter costo brachial Neuralgia (pain in the distribution of inter costo brachial nerve) and Neuroma pain (pain in the region of scar on breast, chest or arm). Radical mastectomy is most disfiguring type of breast cancer surgery and it involves removal of breast, major and minor chest muscles, and lymph nodes [9].

CONCLUSION:

It is concluded that a substantial number of adult

cancer patients were depressed and have a suicidal ideation, causing a significant functional impairment.
