Abstract:

Background: The aim of this study is to find if Viral Lower Respiratory Tract Infections (V-LRTI) occurs more common on top of existing Chronic Lung Diseases (CLD) or has no relation. The study also aimed to learn about the clinical presentation V-LRTI in young children in Jeddah. **Methods:** This was a retrospective study of 136 young patients of 5 years or less who presented to the department of pediatrics at doctor Soliman Fakeeh hospital, Jeddah, diagnosed primarily as LRTI were enrolled in the acute phase and through the chronic stage of the disease. A database was developed to provide the information about preliminary diagnosis, clinical examination, laboratory investigations, treatment and final diagnosis. Among the 136 patients, seven patients lost to follow up and excluded from analysis. Nasopharyngeal Aspirate (NPA) test type was done to identify causative viral infection. End-point was calculated as per protocol on 129 patients. **Results:** A total number of 34 patients out of 129 had positive NPA Viral Test (26%); 19 patients out of the 34 (56%) had CLD & 15 patients (44%) had no CLD. On the other side, 95 patients out of 129 had negative NPA Viral Test (74%); 59 patients out of the 95 (62%) had CLD & 36 patients (38%) had no CLD. The results are not significant (p -value = 0.524). We concluded that there is no significant difference between occurrences of V-LRTI on top of existing CLD. Results show that there is significant difference between V-LRTI & non-V-LRTI presents in the following variables (p -value < 0.05): In V-LRTIs; Age at time of diagnosis is less (0.36 ± 0.31 vs 0.79 ± 0.07), admission to hospital is more (91.2% vs 55.8%), oxygen saturation is less (92.50 ± 3.72 vs 95.96 ± 0.57), Crackles is more (65.6% vs 40.0%) Wheezing is more (71.9% vs 43.2%), Dyspnea is more (44.1% vs 9.5%), and Diarrhea is more (5.9% vs 0.0%).

Conclusion: The study shows that V-LRTI constitutes (27%) with RSV being the commonest causative virus (79.4%). V-LRTI statistically occurs in younger age with more hospitalization. Dyspnea, crackles and wheezing are statistically more frequent in V-LRTI with less Oxygen saturation than Non-V-LRTI. CLD is not a predisposing factor in V-LRTI in preschool age.

INTRODUCTION:

Respiratory tract infection considered as a very common type of infectious disease worldwide. Many viruses cause respiratory tract infection and are identified by a method Polymerase Chain Reaction (PCR). [1]

Acute Lower respiratory tract (LRT) infections are thought to cause nearly 75% of all acute illnesses and are considered the main cause of hospitalization for infants and young children globally. [2,3]

These infections vary depending on the age group, season, underlying disease and upper or lower respiratory tract involvement. [4] Viral respiratory tract infections play a major role as a national health issue due to increased hospital admissions, labor mortalities and school absenteeism of children and the socio-economical affection of viral respiratory infections are observed especially in wintertime. [5,6] Influenza A, Influenza B, Rhinovirus (RV), Respiratory Syncytial Virus (RSV), Corona Virus (CV), Para Influenza Virus (PIV), Human Meta Pneumo Virus (HMPV) and Human Boca Virus (HBOV) are the common cause of viral respiratory tract infections. [7,8] In the last decade, many new respiratory viruses have emerged, including HMPV, new subtypes of Human Corona Viruses (HCoV) and Boca Virus (HBoV). [9]

Acute attacks of severe lower respiratory tract illness are very common in preschoolers, and almost 14% to 26% of preschoolers present with symptoms of recurrent wheezing during the first six years of life. [1,2] These severe attacks are often associated with morbidity, resulting in multiple visits to physicians, and emergency departments. Most of these cases were diagnosed with asthma, and among them, 20.9% seek emergency care, and 6.5% are hospitalized every year. [10]

Children diagnosed with LRT infections with wheezing are more prone to develop recurrent wheezing and/or asthma later in childhood than those having LRT infections without wheezing, even though they are affected by the same virus, previous studies have reported a higher risk for young children who are more likely to have wheezing during or following a viral LRT infection or Chronic Lung Diseases (CLD). [11,12]

In our study, clinical outcomes of patients with acute LRTIs in preschool age were studied to compare between the clinical outcomes of V-LRTI and Non-V-LRTIs with a primary objective to insight whether V-

LRTI occurs more common in preschool children with Chronic Lung Diseases (CLD).

METHODOLOGY:

In this study, we enrolled 136 young patients of 5 years or less, diagnosed primarily as LRTI between January 2008 and January 2009. All the patients were in the acute phase and followed up until cure. Finally, the diagnosis of the presence of chronic lung disease was made.

Study design

This retrospective study involved children 0 to 5 years of age who presented to the pediatric outpatient and emergency departments at doctor Soliman Fakeeh hospital, Jeddah with LRTI and positive respiratory culture for respiratory virus.

The study sample was sourced from virus culture positive specimens. Subsequently, a chart review (emergency department, outpatient and inpatient records) was done on those positive culture cases and those with a diagnosis of LRTI were selected for analysis.

Recognition of pediatric LRTI was based on the physician diagnosis of pneumonia, bronchitis and bronchiolitis. (All medical codes in the at doctor Soliman Fakeeh hospital, Historical Abstracting System, WinRecs that contain the words "pneumonia", "bronchitis" or "bronchiolitis" were included.) Only the first respiratory isolate, during a single clinical event, was included in the analysis. The studied cases did not include readmissions. Participants' demographic, clinical and radiologic findings were collected. Clinical outcome data were assessed according to days of hospitalization, use of mechanical ventilation, and mortality.

The statistician developed a database to provide the following information:

- 1- Patient demographics (initials of a name; date of birth; age, weight and height at presentation; sex, ethnicity; place of residence)
- 2- Detailed clinical history – to include any associated underlying medical condition/s, physical examination on admission, discharge and subsequent medical course over time
- 3- Pertinent laboratory and/or ancillary tests (CXR, CT scan, histopathology, bronchoscopy, capillary blood gases, and pulmonary function tests) at presentation and subsequent clinic follow up.
- 4- Results of Respiratory Virus Test:
Nasopharyngeal Aspirate (NPA) was taken from each patient and tested by Polymerase Chain Reaction (PCR) to detect major respiratory

viruses namely; Influenza A, Influenza B, Respiratory Syncytial Virus (RSV), Rhinovirus, Enterovirus, Parainfluenza 1 2 & 3, Adenovirus, Human Metapneumovirus (HMPV) and Bordetella virus.

- 5- Treatment of supportive therapy, antibiotics or mechanical ventilation
- 6- We follow up cases through the acute phase to cure.

STATISTICAL ANALYSIS:

Frequency distribution using count and percentage were used to describe categorical data and descriptive statistics using appropriate statistics as a mean average, standard deviation, median, lower quartile and upper quartile to describe numerical data.

Chi-square test (or its equivalents) was used to calculate the *p*-value for categorical data while student t-test (or its equivalents) was used to calculate the *p*-value for numerical data. a *p*-value less than or equal to 0.05 is considered significant

FINDINGS & RESULTS:

Tables showing detailed findings; Demography, Significant social history, Clinical Presentation, Signs, Initial Diagnosis, Symptoms, Significant Past Medical History, Investigations, Therapies Interventions, Referral Pattern and Final Diagnosis are presented at the end.

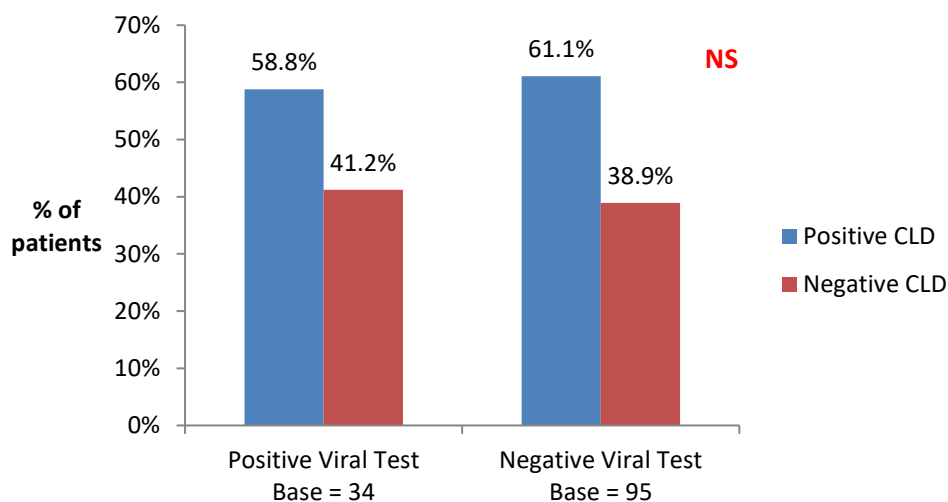

DISCUSSION:

Our study aims to find the relation between occurrences of V-LRTI on top of CLD. It also aims to study the clinical presentation of LRTI and to compare viral versus non-viral infection specifically

We enrolled 136 children of 5 years or less with LRTI between January 2008 and January 2009 in Jeddah with a preliminary diagnosis of LRTI. We proceeded with detailed clinical history, laboratory investigations, and treatment of the acute phase through to cure and diagnose the presence of chronic lung disease. All patients were performed Respiratory Virus Test. Nasopharyngeal Aspirate (NPA) was taken from each patient and tested by Polymerase Chain Reaction (PCR) to detect major respiratory viruses.

- Our study showed that V-LRTI constituted 26.4% (34 patients out of 129 LRTI patients) and Non-V-LRTI constituted 73.6%. Our results near to results obtained by Leena Ravindra et al that showed "Viral antigens were detected in 28.6% of LRTI.
- The primary objective of our study is to find if V_LRTI occurs more common on top of existing CLD or not. Our results showed that 20 (28.8%) out of 34 patients with V-LRTI had CLD whereas 58 (61.1%) out of 95 patients with none-V-LRTI had CLD. The difference is not significant.

Chart 1: Incidence of Viral Lower Respiratory Tract Infection on top of Chronic Lung Disease

- Respiratory syncytial virus (RSV) is the commonest causative virus; it is the causative virus alone in 79.4% of our cases (27 out of 34) and with other viruses in other 5.8% (2 patients). This result matches Leena Ravindra et al. and Gooskens J et al. in which RSV was the commonest cause of V-LRTI.

Chart 2: Causative of virus in 34 V-LRTI patients:

- Our study showed that cases with positive V-LRTI required higher hospital admissions rate 91.2% (31 of 34) compared to 55.8% (53 of 95) in the non-viral group. In studies done by Gooskens et al. [14] and Akturk H et al showed that RSV is the predominate V-LRTI.
- The mean age in our study was 8.20 ± 7.30 (mean \pm SD) months. The mean age in viral group is less than that of non-viral group (4.35 ± 3.71 & 9.70 ± 0.85 respectively). The difference is significant ($p < 0.001$).
- LRTI is more common in males. 61.2% (70 out of 129) were males, and 38.8% were female. The difference in gender between viral & non-viral groups is not significant. Many studies showed that the incidence of LRTI is more common in males. [16,17]
- 23.3% (30 of 129) of cases had a history of sick contacts, and 12.4% had crowded family history (6 persons or more). There is no statistically significant difference between viral & non-viral groups.
- In a study done by Lemke M et al, secondhand (SHS) smoking history was present in 57% of infants. This result is higher than what we have obtained where SHS in our study was 16.3% (21 of 129). There was no statistically significant difference between viral & non-viral groups (23.5%, & 13.7% respectively)
- "Cough" was the predominant symptom. It was a complaint in 98.4% in our sample, this match many other studies. Cough is a symptom in 99.8% Wood et al 99.0% in Michael Harris et al. There was no statistically significant difference between viral & non-viral groups. "Dyspnea" was a complaint in 18.6% (24 of 129 patients). It was 44.1% (15 of 34) in V-LRTI group compared to 9.8% (9 of 95) in Non-V-LRTI group. The differences between other symptoms between the two groups are not significant. The following chart shows the incidence of symptoms in our study

Chart 3 Symptoms by the overall Sample: Base = 129 patients

- 65.1% (84 of 129 patients) needed hospitalization. 31 (37%) out the of 84 patients that admitted to hospital were due to the virus. This result is near to what is given by Michelow IC et al (45%). Admission to hospital is more common in viral group 91.2% (31 of 34) compared to 55.8% (53 of 95) in non-viral group. The difference is statistically significant.

CONCLUSION:

- LRTI is a common disease in preschool age. It is more in males than females (61.2% % 38.8% respectively), and Cough and wheezes are the predominant symptoms.
- V-LRTI constitutes 27% with RSV being the commonest causative virus (79.4%).

- V-LRTI statistically occurs in younger age than Non-V-LRTI (4.35 ± 3.71 & 9.70 ± 0.85 months respectively). Admission to hospital is statistically more in V-LRTI (91.2%) than Non-V-LRTI (55.8%). Dyspnea, crackles and wheezing are statistically more frequent in V-LRTI than Non-V-LRTI with less Oxygen saturation.
- CLD is not a predisposing factor in V-LRTI in preschool age.

Recommendation:

- Study the clinical outcomes of LRTI in a large number of patients.
- Study the effect of existing CLD on the clinical outcomes of LRTI.

Table 12: Final Diagnosis

		Overall Sample		Positive Viral Test		Negative Viral Test		p-value
		Count or Mean	% or SD	Count or Mean	% or SD	Count or Mean	% or SD	
Chronic Lung Disease	Positive CLD	78	60.5%	20	58.8%	58	61.1%	0.820
	Negative CLD	51	39.5%	14	41.2%	37	38.9%
